Premature Ejaculation Numbing SprayiStockphoto

A new spray called PSD502 has been developed that delays premature ejaculation up to six times longer, according to a study of 300 European men. Minute men and disgruntled women everywhere rejoice.

The men were all clinically diagnosed with premature ejaculation and received either a placebo or the spray which contains 7.5 milligrams of lidocaine and 2.5 mg of prilocaine. Five minutes before intercourse, the men sprayed their wangs and used a stopwatch to record the time from penetration to ejaculation. The treatment group went from 0.6 minutes to 3.8 minutes of sex compared one minute in those who used the placebo spray. Seventy-four-percent of the men in the treatment group could last 2 minutes before ejaculating while only 22 percent could last that long in the placebo group.

Hmm...I'm no mathematical genius but doesn't that mean that 26 percent still didn't make a two minute mile? And 3.8 minutes is a victory? If we spray it lots, can we make it twenty? Or just ditch them altogether and spend science funds on vibrator vouchers?

Also, is this spray bad for the ozone? [Health Day]
